CHAPTER 1

Principles

Note: This is a work in progress. Some sections still need to be furnished.

This library focuses on two principles:

- stick to the **tree** structure of Elasticsearch objects
- provide simple and flexible interfaces to make it easy and intuitive to use in an interactive usage

1.1 Elasticsearch tree structures

Many Elasticsearch objects have a **tree** structure, ie they are built from a hierarchy of **nodes**:

- a mapping (tree) is a hierarchy of fields (nodes)
- a query (tree) is a hierarchy of query clauses (nodes)
- an aggregation (tree) is a hierarchy of aggregation clauses (nodes)
- an aggregation response (tree) is a hierarchy of response buckets (nodes)

This library sticks to that structure by providing a flexible syntax distinguishing **trees** and **nodes**, **trees** all inherit from lighttree.Tree class, whereas nodes all inherit from lighttree.Node class.

1.2 Interactive usage

pandagg is designed for both for "regular" code repository usage, and "interactive" usage (ipython or jupyter notebook usage with autocompletion features inspired by pandas design).

Some classes are not intended to be used elsewhere than in interactive mode (ipython), since their purpose is to serve auto-completion features and convenient representations.

Namely:

- *IMapping*: used to interactively navigate in mapping and run quick aggregations on some fields
- *IResponse*: used to interactively navigate in an aggregation response

These use case will be detailed in following sections.

CHAPTER 2

User Guide

Note: Examples will be based on *IMDB dataset* data. This is a work in progress. Some sections still need to be furnished.

2.1 Query

The *Query* class provides :

- multiple syntaxes to declare and udpate a query
- query validation (with nested clauses validation)
- ability to insert clauses at specific points
- tree-like visual representation

2.1.1 Instantiation

2.1.1.1 From native "dict" query

Given the following query:

```
>>> expected_query = {'bool': {'must': [
>>>     {'terms': {'genres': ['Action', 'Thriller']}},
>>>     {'range': {'rank': {'gte': 7}}},
>>>     {'nested': {
>>>         'path': 'roles',
>>>         'query': {'bool': {'must': [
>>>             {'term': {'roles.gender': {'value': 'F'}}},
>>>             {'term': {'roles.role': {'value': 'Reporter'}}}]}}
>>>          }
```

(continues on next page)

(continued from previous page)

```
>>>     }}
>>> ]}}
```

To instantiate *Query*, simply pass "dict" query as argument:

```
>>> from pandagg.query import Query
>>> q = Query(expected_query)
```

A visual representation of the query is available with *show()*:

```
>>> q.show()
<Query>
bool
└── must
    ├── nested, path="roles"
    │   └── query
    │       └── bool
    │           └── must
    │               ├── term, field=roles.gender, value="F"
    │               └── term, field=roles.role, value="Reporter"
    ├── range, field=rank, gte=7
    └── terms, genres=["Action", "Thriller"]
```

Call *to_dict()* to convert it to native dict:

```
>>> q.to_dict()
{'bool': {
    'must': [
        {'range': {'rank': {'gte': 7}}},
        {'terms': {'genres': ['Action', 'Thriller']}},
        {'bool': {'must': [
            {'term': {'roles.role': {'value': 'Reporter'}}},
            {'term': {'roles.gender': {'value': 'F'}}}]}}]}}
        ]}
    ]
}}
```

```
>>> from pandagg.utils import equal_queries
>>> equal_queries(q.to_dict(), expected_query)
True
```

Note: *equal_queries* function won't consider order of clauses in must/should parameters since it actually doesn't matter in Elasticsearch execution, ie

```
>>> equal_queries({'must': [A, B]}, {'must': [B, A]})
True
```

2.1.1.2 With DSL classes

Pandagg provides a DSL to declare this query in a quite similar fashion:

```
>>> from pandagg.query import Nested, Bool, Range, Term, Terms
```

```
>>> q = Bool(must=[
>>>     Terms(genres=['Action', 'Thriller']),
>>>     Range(rank={"gte": 7}),
>>>     Nested(
>>>         path='roles',
>>>         query=Bool(must=[
>>>             Term(roles__gender='F'),
>>>             Term(roles__role='Reporter')
>>>         ])
>>>     )
>>> ])
```

All these classes inherit from *Query* and thus provide the same interface.

```
>>> from pandagg.query import Query
>>> isinstance(q, Query)
True
```

2.1.1.3 With single clause as flattened syntax

In the flattened syntax, the query clause type is used as first argument:

```
>>> from pandagg.query import Query
>>> q = Query('terms', genres=['Action', 'Thriller'])
```

2.1.2 Query enrichment

All methods described below return a new *Query* instance, and keep unchanged the initial query.

For instance:

```
>>> from pandagg.query import Query
>>> initial_q = Query()
>>> enriched_q = initial_q.query('terms', genres=['Comedy', 'Short'])
```

```
>>> initial_q.to_dict()
None
```

```
>>> enriched_q.to_dict()
{'terms': {'genres': ['Comedy', 'Short']}}
```

Note: Calling *to_dict()* on an empty Query returns *None*

```
>>> from pandagg.query import Query
>>> Query().to_dict()
None
```

2.1.2.1 query() method

The base method to enrich a *Query* is *query()*.

Considering this query:

```
>>> from pandagg.query import Query
>>> q = Query()
```

query() accepts following syntaxes:

from dictionnary:

```
>>> q.query({"terms": {"genres": ['Comedy', 'Short']})
```

flattened syntax:

```
>>> q.query("terms", genres=['Comedy', 'Short'])
```

from Query instance (this includes DSL classes):

```
>>> from pandagg.query import Terms
>>> q.query(Terms(genres=['Action', 'Thriller']))
```

2.1.2.2 Compound clauses specific methods

Query instance also exposes following methods for specific compound queries:

(TODO: detail allowed syntaxes)

Specific to bool queries:

- *bool()*
- *filter()*
- *must()*
- *must_not()*
- *should()*

Specific to other compound queries:

- *nested()*
- *constant_score()*
- *dis_max()*
- *function_score()*
- *has_child()*
- *has_parent()*
- *parent_id()*
- *pinned_query()*
- *script_score()*
- *boost()*

2.1.2.3 Inserted clause location

On all insertion methods detailed above, by default, the inserted clause is placed at the top level of your query, and generates a bool clause if necessary.

Considering the following query:

```
>>> from pandagg.query import Query
>>> q = Query('terms', genres=['Action', 'Thriller'])
>>> q.show()
<Query>
terms, genres=["Action", "Thriller"]
```

A bool query will be created:

```
>>> q = q.query('range', rank={"gte": 7})
>>> q.show()
<Query>
bool
└── must
    ├── range, field=rank, gte=7
    └── terms, genres=["Action", "Thriller"]
```

And reused if necessary:

```
>>> q = q.must_not('range', year={"lte": 1970})
>>> q.show()
<Query>
bool
├── must
│   ├── range, field=rank, gte=7
│   └── terms, genres=["Action", "Thriller"]
└── must_not
    └── range, field=year, lte=1970
```

Specifying a specific location requires to name queries :

```
>>> from pandagg.query import Nested
```

```
>>> q = q.nested(path='roles', _name='nested_roles', query=Term('roles.gender', value=
↪'F'))
>>> q.show()
<Query>
bool
├── must
│   ├── nested, _name=nested_roles, path="roles"
│   │   └── query
│   │       └── term, field=roles.gender, value="F"
│   ├── range, field=rank, gte=7
│   └── terms, genres=["Action", "Thriller"]
└── must_not
    └── range, field=year, lte=1970
```

Doing so allows to insert clauses above/below given clause using *parent*/*child* parameters:

```
>>> q = q.query('term', roles__role='Reporter', parent='nested_roles')
>>> q.show()
```

(continues on next page)

(continued from previous page)

```
<Query>
bool
├── must
│   ├── nested, _name=nested_roles, path="roles"
│   │   └── query
│   │       └── bool
│   │           └── must
│   │               ├── term, field=roles.role, value="Reporter"
│   │               └── term, field=roles.gender, value="F"
│   ├── range, field=rank, gte=7
│   └── terms, genres=["Action", "Thriller"]
└── must_not
    └── range, field=year, lte=1970
```

TODO: explain *parent_param*, *child_param*, *mode* merging strategies on same named clause etc..

2.2 Aggregation

The *Aggs* class provides :

- multiple syntaxes to declare and udpate a aggregation
- clause validation (with nested clauses validation)
- ability to insert clauses at specific points

2.2.1 Aggregation declaration

2.2.2 Aggregation response

TODO

2.3 Search

TODO

2.4 Mapping

2.4.1 Interactive mapping

In interactive context, the *IMapping* class provides navigation features with autocompletion to quickly discover a large mapping:

```
>>> from pandagg.mapping import IMapping
>>> from examples.imdb.load import mapping
>>> m = IMapping(imdb_mapping)
>>> m.roles
<IMapping subpart: roles>
roles                                                  [Nested]
```

(continues on next page)

(continued from previous page)

```
├── actor_id                                                Integer
├── first_name                                              Text
│   └── raw                                               ~ Keyword
├── gender                                                  Keyword
├── last_name                                               Text
│   └── raw                                               ~ Keyword
└── role                                                    Keyword
>>> m.roles.first_name
<IMapping subpart: roles.first_name>
first_name                                              Text
└── raw                                               ~ Keyword
```

To get the complete field definition, just call it:

```
>>> m.roles.first_name()
<Mapping Field first_name> of type text:
{
    "type": "text",
    "fields": {
        "raw": {
            "type": "keyword"
        }
    }
}
```

A **IMapping** instance can be bound to an Elasticsearch client to get quick access to aggregations computation on mapping fields.

Suppose you have the following client:

```
>>> from elasticsearch import Elasticsearch
>>> client = Elasticsearch(hosts=['localhost:9200'])
```

Client can be bound at instantiation:

```
>>> m = IMapping(imdb_mapping, client=client, index_name='movies')
```

Doing so will generate a **a** attribute on mapping fields, this attribute will list all available aggregation for that field type (with autocompletion):

```
>>> m.roles.gender.a.terms()
[('M', {'key': 'M', 'doc_count': 2296792}),
('F', {'key': 'F', 'doc_count': 1135174})]
```

Note: Nested clauses will be automatically taken into account.

2.5 Cluster indices discovery

TODO

CHAPTER 3

Advanced usage

Note: This is a work in progress. Some sections still need to be furnished.

- node and tree deserialization order
- compound query insertion

CHAPTER 4

IMDB dataset

You might know the Internet Movie Database, commonly called IMDB.

Well it's a simple example to showcase some of Elasticsearch capabilities.

In this case, relational databases (SQL) are a good fit to store with consistence this kind of data. Yet indexing some of this data in a optimized search engine will allow more powerful queries.

4.1 Query requirements

In this example, we'll suppose most usage/queries requirements will be around the concept of movie (rather than usages focused on fetching actors or directors, even though it will still be possible with this data structure).

The index should provide good performances trying to answer these kind question (non-exhaustive):

- in which movies this actor played?
- what movies genres were most popular among decades?
- which actors have played in best-rated movies, or worst-rated movies?
- which actors movies directors prefer to cast in their movies?
- which are best ranked movies of last decade in Action or Documentary genres?
- ...

4.2 Data source

I exported following SQL tables from MariaDB following these instructions.

Relational schema is the following:

imdb tables

4.3 Index mapping

4.3.1 Overview

The base unit (document) will be a movie, having a name, rank (ratings), year of release, a list of actors and a list of directors.

Schematically:

```
Movie:
 - name
 - year
 - rank
 - [] genres
 - [] directors
 - [] actor roles
```

4.3.2 Which fields require nesting?

Since genres contain a single keyword field, in no case we need it to be stored as a nested field. On the contrary, actor roles and directors require a nested mapping if we consider applying multiple simultanous query clauses on their sub-fields (for instance search movie in which actor is a woman AND whose role is nurse). More information on distinction between array and nested fields here.

4.3.3 Text or keyword fields?

Some fields are easy to choose, in no situation gender will require a full text search, thus we'll store it as a keyword. On the other hand actors and directors names (first and last) will require full-text search, we'll thus opt for a text field. Yet we might want to aggregate on exact keywords to count number of movies per actor for instance. More inforamtion on distinction between text and keyword fields here

4.3.4 Mapping

```
<Mapping>
_
├── directors                                                [Nested]
│   ├── director_id                                           Keyword
│   ├── first_name                                            Text
│   │   └── raw                                            ~ Keyword
│   ├── full_name                                             Text
│   │   └── raw                                            ~ Keyword
│   ├── genres                                                Keyword
│   └── last_name                                             Text
│       └── raw                                            ~ Keyword
├── genres                                                    Keyword
├── movie_id                                                  Keyword
├── name                                                      Text
│   └── raw                                                ~ Keyword
├── nb_directors                                              Integer
├── nb_roles                                                  Integer
├── rank                                                      Float
├── roles                                                    [Nested]
```

(continues on next page)

(continued from previous page)

```
│   ├── actor_id                                          Keyword
│   ├── first_name                                        Text
│   │   └── raw                                         ~ Keyword
│   ├── full_name                                         Text
│   │   └── raw                                         ~ Keyword
│   ├── gender                                            Keyword
│   ├── last_name                                         Text
│   │   └── raw                                         ~ Keyword
│   └── role                                              Keyword
└── year                                                  Integer
```

4.4 Steps to start playing with your index

Note to Elastic, if you have a spare cluster to prepare demo indices on which you could let your community perform read operations we could skip this step ;)

4.4.1 Dump tables

Follow instruction on bottom of https://relational.fit.cvut.cz/dataset/IMDb page and dump following tables in a directory:

- movies.csv
- movies_genres.csv
- movies_directors.csv
- directors.csv
- directors_genres.csv
- roles.csv
- actors.csv

4.4.2 Clone pandagg and setup environment

```
git clone git@github.com:alkemics/pandagg.git
cd pandagg

virtualenv env
python setup.py develop
pip install pandas simplejson jupyter seaborn
```

Then copy `conf.py.dist` file into `conf.py` and edit variables as suits you, for instance:

```
# your cluster address
ES_HOST = 'localhost:9200'

# where your table dumps are stored, and where serialized output will be written
DATA_DIR = '/path/to/dumps/'
OUTPUT_FILE_NAME = 'serialized.json'
```

4.4.3 Serialize movie documents and insert them

```
# generate serialized movies documents, ready to be inserted in ES
# can take a while
python examples/imdb/serialize.py

# create index with mapping if necessary, bulk insert documents in ES
python examples/imdb/load.py
```

4.4.4 Explore pandagg notebooks

An example notebook is available to showcase some of `pandagg` functionalities: here it is.

Code is present in `examples/imdb/IMDB exploration.py` file.

CHAPTER 5

pandagg package

5.1 Subpackages

5.1.1 pandagg.interactive package

5.1.1.1 Submodules

pandagg.interactive.mapping module

class pandagg.interactive.mapping.**IMapping**(**args*, ***kwargs*)

Bases: lighttree.interactive.TreeBasedObj

Interactive wrapper upon mapping tree, allowing field navigation and quick access to single clause aggregations computation.

pandagg.interactive.response module

class pandagg.interactive.response.**IResponse**(*tree*, *client=None*, *index_name=None*, *root_path=None*, *depth=None*, *initial_tree=None*, *query=None*)

Bases: lighttree.interactive.TreeBasedObj

Interactive aggregation response.

get_bucket_filter()

Build filters to select documents belonging to that bucket

list_documents(***body*)

Return ES aggregation query to list documents belonging to given bucket. :return:

5.1.1.2 Module contents

5.1.2 pandagg.node package

5.1.2.1 Subpackages

pandagg.node.aggs package

Submodules

pandagg.node.aggs.abstract module

class pandagg.node.aggs.abstract.**AggNode**(*name*, *meta=None*, ***body*)
Bases: pandagg.node._node.Node

Wrapper around elasticsearch aggregation concept. https://www.elastic.co/guide/en/elasticsearch/reference/2.3/search-aggregations.html

Each aggregation can be seen both a Node that can be encapsulated in a parent agg.

Define a method to build aggregation request.

BLACKLISTED_MAPPING_TYPES = None

KEY = None

VALUE_ATTRS = None

WHITELISTED_MAPPING_TYPES = None

classmethod extract_bucket_value(*response*, *value_as_dict=False*)

extract_buckets(*response_value*)

get_filter(*key*)
Return filter query to list documents having this aggregation key. :param key: string :return: elasticsearch filter query

line_repr(*depth*, ***kwargs*)
Control how node is displayed in tree representation.

to_dict(*with_name=False*)
ElasticSearch aggregation queries follow this formatting:

```
{
    "<aggregation_name>" : {
        "<aggregation_type>" : {
            <aggregation_body>
        }
        [,"meta" : {  [<meta_data_body>] } ]?
    }
}
```

Query dict returns the following part (without aggregation name):

```
{
    "<aggregation_type>" : {
        <aggregation_body>
    }
```

(continues on next page)

(continued from previous page)

```
    [,"meta" : {  [<meta_data_body>] } ]?
}
```

classmethod valid_on_field_type(*field_type*)

class pandagg.node.aggs.abstract.**BucketAggNode**(*name*, *meta=None*, ***body*)
Bases: *pandagg.node.aggs.abstract.AggNode*

Bucket aggregation have special abilities: they can encapsulate other aggregations as children. Each time, the extracted value is a 'doc_count'.

Provide methods: - to build aggregation request (with children aggregations) - to to extract buckets from raw response - to build query to filter documents belonging to that bucket

Note: the aggs attribute's only purpose is for children initiation with the following syntax: >>> from pandagg.aggs import Terms, Avg >>> agg = Terms(>>> name='term_agg', >>> field='some_path', >>> aggs=[>>> Avg(agg_name='avg_agg', field='some_other_path') >>>] >>>)

VALUE_ATTRS = None

extract_buckets(*response_value*)

get_filter(*key*)
Provide filter to get documents belonging to document of given key.

class pandagg.node.aggs.abstract.**FieldOrScriptMetricAgg**(*name*, *meta=None*, ***body*)
Bases: *pandagg.node.aggs.abstract.MetricAgg*

Metric aggregation based on single field.

VALUE_ATTRS = None

class pandagg.node.aggs.abstract.**MetricAgg**(*name*, *meta=None*, ***body*)
Bases: *pandagg.node.aggs.abstract.AggNode*

Metric aggregation are aggregations providing a single bucket, with value attributes to be extracted.

VALUE_ATTRS = None

extract_buckets(*response_value*)

get_filter(*key*)
Return filter query to list documents having this aggregation key. :param key: string :return: elasticsearch filter query

class pandagg.node.query.abstract.**FlatFieldQueryClause**(*field*, *_name=None*, ***body*)
Bases: *pandagg.node.query.abstract.AbstractSingleFieldQueryClause*

Query clause applied on one single field. Example:

Exists: {"exists": {"field": "user"}} -> field = "user" -> body = {"field": "user"} q = Exists(field="user")

DistanceFeature: {“distance_feature”: {“field”: “production_date”, “pivot”: “7d”, “origin”: “now”}} -> field = “production_date” -> body = {“field”: “production_date”, “pivot”: “7d”, “origin”: “now”} q = DistanceFeature(field=”production_date”, pivot=”7d”, origin=”now”)

class pandagg.node.query.abstract.**KeyFieldQueryClause**(*field=None*, *_name=None*, *_expand__to_dot=True*, ***params*)

Bases: *pandagg.node.query.abstract.AbstractSingleFieldQueryClause*

Clause with field used as key in clause body:

Term: {“term”: {“user”: {“value”: “Kimchy”, “boost”: 1}}} -> field = “user” -> body = {“user”: {“value”: “Kimchy”, “boost”: 1}} q1 = Term(user={“value”: “Kimchy”, “boost”: 1}) q2 = Term(field=”user”, value=”Kimchy”, boost=1}})

Can accept a “_implicit_param” attribute specifying which is the equivalent key when inner body isn’t a dict but a raw value. For Term: _implicit_param = “value” q = Term(user=”Kimchy”) {“term”: {“user”: {“value”: “Kimchy”}}} -> field = “user” -> body = {“term”: {“user”: {“value”: “Kimchy”}}}

Module contents

pandagg.node.response package

Submodules

pandagg.node.response.bucket module

class pandagg.node.response.bucket.**Bucket**(*value*, *key=None*, *level=None*)
Bases: pandagg.node._node.Node

ROOT_NAME = 'root'

attr_name
Determine under which attribute name the bucket will be available in response tree. Dots are replaced by _ characters so that they don't prevent from accessing as attribute.

Resulting attribute unfit for python attribute name syntax is still possible and will be accessible through item access (dict like), see more in 'utils.Obj' for more details.

line_repr(***kwargs*)
Control how node is displayed in tree representation.

Module contents

5.1.2.2 Submodules

pandagg.node.types module

5.1.2.3 Module contents

5.1.3 pandagg.tree package

5.1.3.1 Subpackages

pandagg.tree.aggs package

Submodules

pandagg.tree.aggs.aggs module

class pandagg.tree.aggs.aggs.**AbstractLeafAgg**(**args*, ***kwargs*)
Bases: *pandagg.tree.aggs.aggs.Aggs*

KEY = None
Allow following syntax:

```
>>> a = Avg("my_terms_agg", field="yolo")
```

class pandagg.tree.aggs.aggs.**AbstractParentAgg**(**args*, ***kwargs*)
Bases: *pandagg.tree.aggs.aggs.Aggs*

KEY = None
Allow following syntax:

```
>>> a = Terms("my_terms_agg", field="yolo", aggs={...})
```

class pandagg.tree.aggs.aggs.**Aggs**(**args*, ***kwargs*)
Bases: pandagg.tree._tree.Tree

Combination of aggregation clauses. This class provides handful methods to build an aggregation (see aggs() and groupby()), and is used as well to parse aggregations response in handy formats.

Mapping declaration is optional, but doing so validates aggregation validity and automatically handles missing nested clauses.

All following syntaxes are identical:

From a dict:

```
>>> Aggs({"per_user":{"terms":{"field":"user"}}})
```

Using shortcut declaration: first argument is the aggregation type, other arguments are aggregation body parameters:

```
>>> Aggs('terms', name='per_user', field='user')
```

Using DSL class:

```
>>> from pandagg.aggs import Terms
>>> Aggs(Terms('per_user', field='user'))
```

Dict and DSL class syntaxes allow to provide multiple clauses aggregations:

```
>>> Aggs({"per_user":{"terms":{"field":"user"}, "aggs": {"avg_age": {"avg": {
↪"field": "age"}}}}})
```

Which is similar to:

```
>>> from pandagg.aggs import Terms, Avg
>>> Terms('per_user', field='user', aggs=Avg('avg_age', field='age'))
```

Keyword Arguments

- *mapping* (dict or pandagg.tree.mapping.Mapping) – Mapping of requested indice(s). Providing it will validate aggregations validity, and add required nested clauses if missing.
- *nested_autocorrect* (bool) – In case of missing nested clauses in aggregation, if True, automatically add missing nested clauses, else raise error.
- remaining kwargs: Used as body in aggregation

aggs(**args*, ***kwargs*)
Arrange passed aggregations "horizontally".

Given the initial aggregation:

```
A──> B
└──> C
```

If passing multiple aggregations with *insert_below* = 'A':

```
A──> B
└──> C
└──> new1
└──> new2
```

Note: those will be placed under the *insert_below* aggregation clause id if provided, else under the deepest linear bucket aggregation if there is no ambiguity:

OK:

```
A──> B -> C -> new
```

KO:

```
A──> B
└──> C
```

args accepts single occurrence or sequence of following formats:

- string (for terms agg concise declaration)
- regular Elasticsearch dict syntax
- AggNode instance (for instance Terms, Filters etc)

Keyword Arguments

- *insert_below* (`string`) – Parent aggregation name under which these aggregations should be placed
- *at_root* (`string`) – Insert aggregations at root of aggregation query
- remaining kwargs: Used as body in aggregation

Return type *pandagg.aggs.Aggs*

applied_nested_path_at_node(*nid*)

deepest_linear_bucket_agg

Return deepest bucket aggregation node (pandagg.nodes.abstract.BucketAggNode) of that aggregation that neither has siblings, nor has an ancestor with siblings.

groupby(**args*, ***kwargs*)

Arrange passed aggregations in vertical/nested manner, above or below another agg clause.

Given the initial aggregation:

```
A──> B
└──> C
```

If *insert_below* = 'A':

```
A──> new──> B
      └──> C
```

If *insert_above* = 'B':

```
A──> new──> B
└──> C
```

by argument accepts single occurrence or sequence of following formats:

- string (for terms agg concise declaration)
- regular Elasticsearch dict syntax
- AggNode instance (for instance Terms, Filters etc)

If *insert_below* nor *insert_above* is provided by will be placed between the the deepest linear bucket aggregation if there is no ambiguity, and its children:

```
A──> B       : OK generates      A──> B -> C -> by

A──> B       : KO, ambiguous, must precise either A, B or C
└──> C
```

Accepted all Aggs.__init__ syntaxes

```
>>> Aggs()\
>>> .groupby('terms', name='per_user_id', field='user_id')
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Passing a dict:

```
>>> Aggs().groupby({"terms_on_my_field":{"terms":{"field":"some_field"}}})
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Using DSL class:

```
>>> from pandagg.aggs import Terms
>>> Aggs().groupby(Terms('terms_on_my_field', field='some_field'))
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Shortcut syntax for terms aggregation: creates a terms aggregation, using field as aggregation name

```
>>> Aggs().groupby('some_field')
{"some_field":{"terms":{"field":"some_field"}}}
```

Using a Aggs object:

```
>>> Aggs().groupby(Aggs('per_user_id', 'terms', field='user_id'))
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Accepted declarations for multiple aggregations:

Keyword Arguments

- *insert_below* (`string`) – Parent aggregation name under which these aggregations should be placed
- *insert_above* (`string`) – Aggregation name above which these aggregations should be placed
- *at_root* (`string`) – Insert aggregations at root of aggregation query
- remaining kwargs: Used as body in aggregation

Return type *pandagg.aggs.Aggs*

node_class
alias of *pandagg.node.aggs.abstract.AggNode*

show(**args*, ***kwargs*)
Return tree structure in hierarchy style.

Parameters

- **nid** – Node identifier from which tree traversal will start. If None tree root will be used
- **filter_** – filter function performed on nodes. Nodes excluded from filter function nor their children won't be displayed
- **reverse** – the `reverse` param for sorting `Node` objects in the same level
- **key** – key used to order nodes of same parent
- **reverse** – reverse parameter applied at sorting
- **line_type** – display type choice
- **limit** – int, truncate tree display to this number of lines
- **kwargs** – kwargs params passed to node `line_repr` method

Return type unicode in python2, str in python3

Bases: pandagg.tree._tree.Tree

Combination of query clauses.

Mapping declaration is optional, but doing so validates query validity and automatically inserts nested clauses when necessary.

Keyword Arguments

- *mapping* (`dict` or `pandagg.tree.mapping.Mapping`) – Mapping of requested indice(s). Providing it will add validation features, and add required nested clauses if missing.
- *nested_autocorrect* (`bool`) – In case of missing nested clauses in query, if True, automatically add missing nested clauses, else raise error.
- remaining kwargs: Used as body in query clauses.

KEY = None

applied_nested_path_at_node(*nid*)

bool(**args*, ***kwargs*)

boost(**args*, ***kwargs*)

constant_score(**args*, ***kwargs*)

dis_max(**args*, ***kwargs*)

filter(**args*, ***kwargs*)

function_score(**args*, ***kwargs*)

has_child(**args*, ***kwargs*)

has_parent(**args*, ***kwargs*)

must(**args*, ***kwargs*)

must_not(**args*, ***kwargs*)

nested(**args*, ***kwargs*)

node_class
alias of *pandagg.node.query.abstract.QueryClause*

parent_id(**args*, ***kwargs*)

pinned_query(**args*, ***kwargs*)

query(**args*, ***kwargs*)
Insert new clause(s) in current query.

Inserted clause can accepts following syntaxes.

Given an empty query:

```
>>> from pandagg.query import Query
>>> q = Query()
```

flat syntax: clause type, followed by query clause body as keyword arguments:

```
>>> q.query('term', some_field=23)
{'term': {'some_field': 23}}
```

from regular Elasticsearch dict query:

```
>>> q.query({'term': {'some_field': 23}})
{'term': {'some_field': 23}}
```

using pandagg DSL:

```
>>> from pandagg.query import Term
>>> q.query(Term(field=23))
{'term': {'some_field': 23}}
```

Keyword Arguments

- *parent* (`str`) – named query clause under which the inserted clauses should be placed.
- *parent_param* (`str` optional parameter when using *parent* param) – parameter under which inserted clauses will be placed. For instance if *parent* clause is a boolean, can be 'must', 'filter', 'should', 'must_not'.
- *child* (`str`) – named query clause above which the inserted clauses should be placed.
- *child_param* (`str` optional parameter when using *parent* param) – parameter of inserted boolean clause under which child clauses will be placed. For instance if inserted clause is a boolean, can be 'must', 'filter', 'should', 'must_not'.
- *mode* (`str` one of 'add', 'replace', 'replace_all') – merging strategy when inserting clauses on a existing compound clause.
  - 'add' (default) : adds new clauses keeping initial ones
  - 'replace' : for each parameter (for instance in 'bool' case : 'filter', 'must', 'must_not', 'should'), replace existing clauses under this parameter, by new ones only if declared in inserted compound query
  - 'replace_all' : existing compound clause is completely replaced by the new one

script_score(**args*, ***kwargs*)

should(**args*, ***kwargs*)

show(**args*, ***kwargs*)

Return tree structure in hierarchy style.

Parameters

- **nid** – Node identifier from which tree traversal will start. If None tree root will be used
- **filter_** – filter function performed on nodes. Nodes excluded from filter function nor their children won't be displayed
- **reverse** – the `reverse` param for sorting `Node` objects in the same level
- **key** – key used to order nodes of same parent
- **reverse** – reverse parameter applied at sorting
- **line_type** – display type choice
- **limit** – int, truncate tree display to this number of lines
- **kwargs** – kwargs params passed to node `line_repr` method

Return type unicode in python2, str in python3

to_dict(*from_=None*, *with_name=True*)

Serialize query as native dict. :param from_: optional, :param with_name: optional :return:

Module contents

5.1.3.2 Submodules

pandagg.tree.mapping module

class pandagg.tree.mapping.**Mapping**(**args*, ***kwargs*)
Bases: pandagg.tree._tree.Tree

KEY = None

get(*key*)
Get a node by its id. :param nid: str, identifier of node to fetch :rtype: lighttree.node.Node

list_nesteds_at_field(*field_path*)

mapping_type_of_field(*field_path*)

nested_at_field(*field_path*)

node_class
alias of *pandagg.node.mapping.abstract.Field*

node_path(*nid*)

resolve_path_to_id(*path*)

to_dict(*from_=None*, *depth=None*)

validate_agg_node(*agg_node*, *exc=True*)
Ensure if node has field or path that it exists in mapping, and that required aggregation type if allowed on this kind of field. :param agg_node: AggNode you want to validate on this mapping :param exc: boolean, if set to True raise exception if invalid :rtype: boolean

pandagg.tree.response module

class pandagg.tree.response.**AggsResponseTree**(*aggs*, *index*)
Bases: pandagg.tree._tree.Tree

Tree representation of an ElasticSearch response.

bucket_properties(*bucket*, *properties=None*, *end_level=None*, *depth=None*)
Recursive method returning a given bucket's properties in the form of an ordered dictionnary. Travel from current bucket through all ancestors until reaching root.

Parameters

- **bucket** – instance of pandagg.buckets.buckets.Bucket
- **properties** – OrderedDict accumulator of 'level' -> 'key'
- **end_level** – optional parameter to specify until which level properties are fetched
- **depth** – optional parameter to specify a limit number of levels which are fetched

Returns OrderedDict of structure 'level' -> 'key'

get_bucket_filter(*nid*)
Build query filtering documents belonging to that bucket. Suppose the following configuration:

```
Base                          <- filter on base
  |── Nested_A                   no filter on A (nested still must be applied␣
↪for children)
  |     |── SubNested A1
  |     └── SubNested A2        <- filter on A2
  └── Nested_B                  <- filter on B
```

parse(*raw_response*)
Build response tree from ElasticSearch aggregation response

Note: if the root aggregation node can generate multiple buckets, a response root is crafted to avoid having multiple roots.

Parameters **raw_response** – ElasticSearch aggregation response

Returns self

show(***kwargs*)
Return tree structure in hierarchy style.

Parameters

- **nid** – Node identifier from which tree traversal will start. If None tree root will be used
- **filter_** – filter function performed on nodes. Nodes excluded from filter function nor their children won't be displayed

- **reverse** – the `reverse` param for sorting `Node` objects in the same level
- **key** – key used to order nodes of same parent
- **reverse** – reverse parameter applied at sorting
- **line_type** – display type choice
- **limit** – int, truncate tree display to this number of lines
- **kwargs** – kwargs params passed to node `line_repr` method

Return type unicode in python2, str in python3

5.1.3.3 Module contents

5.2 Submodules

5.2.1 pandagg.aggs module

class `pandagg.aggs.`**Aggs**(**args*, ***kwargs*)

Bases: `pandagg.tree._tree.Tree`

Combination of aggregation clauses. This class provides handful methods to build an aggregation (see `aggs()` and `groupby()`), and is used as well to parse aggregations response in handy formats.

Mapping declaration is optional, but doing so validates aggregation validity and automatically handles missing nested clauses.

All following syntaxes are identical:

From a dict:

```
>>> Aggs({"per_user":{"terms":{"field":"user"}}})
```

Using shortcut declaration: first argument is the aggregation type, other arguments are aggregation body parameters:

```
>>> Aggs('terms', name='per_user', field='user')
```

Using DSL class:

```
>>> from pandagg.aggs import Terms
>>> Aggs(Terms('per_user', field='user'))
```

Dict and DSL class syntaxes allow to provide multiple clauses aggregations:

```
>>> Aggs({"per_user":{"terms":{"field":"user"}, "aggs": {"avg_age": {"avg": {
↪"field": "age"}}}}})
```

Which is similar to:

```
>>> from pandagg.aggs import Terms, Avg
>>> Terms('per_user', field='user', aggs=Avg('avg_age', field='age'))
```

Keyword Arguments

- *mapping* (`dict` or `pandagg.tree.mapping.Mapping`) – Mapping of requested indice(s). Providing it will validate aggregations validity, and add required nested clauses if missing.
- *nested_autocorrect* (`bool`) – In case of missing nested clauses in aggregation, if True, automatically add missing nested clauses, else raise error.
- remaining kwargs: Used as body in aggregation

aggs(**args*, ***kwargs*)

Arrange passed aggregations "horizontally".

Given the initial aggregation:

```
A──> B
└──> C
```

If passing multiple aggregations with *insert_below* = 'A':

```
A──> B
└──> C
└──> new1
└──> new2
```

Note: those will be placed under the *insert_below* aggregation clause id if provided, else under the deepest linear bucket aggregation if there is no ambiguity:

OK:

```
A──> B ─> C ─> new
```

KO:

```
A──> B
└──> C
```

args accepts single occurrence or sequence of following formats:

- string (for terms agg concise declaration)
- regular Elasticsearch dict syntax
- AggNode instance (for instance Terms, Filters etc)

Keyword Arguments

- *insert_below* (`string`) – Parent aggregation name under which these aggregations should be placed
- *at_root* (`string`) – Insert aggregations at root of aggregation query
- remaining kwargs: Used as body in aggregation

Return type *pandagg.aggs.Aggs*

applied_nested_path_at_node(*nid*)

deepest_linear_bucket_agg

Return deepest bucket aggregation node (pandagg.nodes.abstract.BucketAggNode) of that aggregation that neither has siblings, nor has an ancestor with siblings.

groupby (**args*, ***kwargs*)

Arrange passed aggregations in vertical/nested manner, above or below another agg clause.

Given the initial aggregation:

```
A──> B
└──> C
```

If *insert_below* = 'A':

```
A──> new──> B
      └──> C
```

If *insert_above* = 'B':

```
A──> new──> B
└──> C
```

by argument accepts single occurrence or sequence of following formats:

- string (for terms agg concise declaration)
- regular Elasticsearch dict syntax
- AggNode instance (for instance Terms, Filters etc)

If *insert_below* nor *insert_above* is provided by will be placed between the the deepest linear bucket aggregation if there is no ambiguity, and its children:

```
A──> B       : OK generates      A──> B -> C -> by

A──> B       : KO, ambiguous, must precise either A, B or C
└──> C
```

Accepted all Aggs.__init__ syntaxes

```
>>> Aggs()\
>>> .groupby('terms', name='per_user_id', field='user_id')
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Passing a dict:

```
>>> Aggs().groupby({"terms_on_my_field":{"terms":{"field":"some_field"}}})
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Using DSL class:

```
>>> from pandagg.aggs import Terms
>>> Aggs().groupby(Terms('terms_on_my_field', field='some_field'))
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Shortcut syntax for terms aggregation: creates a terms aggregation, using field as aggregation name

```
>>> Aggs().groupby('some_field')
{"some_field":{"terms":{"field":"some_field"}}}
```

Using a Aggs object:

```
>>> Aggs().groupby(Aggs('per_user_id', 'terms', field='user_id'))
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Accepted declarations for multiple aggregations:

Keyword Arguments

- *insert_below* (`string`) – Parent aggregation name under which these aggregations should be placed
- *insert_above* (`string`) – Aggregation name above which these aggregations should be placed
- *at_root* (`string`) – Insert aggregations at root of aggregation query
- remaining kwargs: Used as body in aggregation

Return type *pandagg.aggs.Aggs*

node_class
alias of *pandagg.node.aggs.abstract.AggNode*

show(**args*, ***kwargs*)
Return tree structure in hierarchy style.

Parameters

- **nid** – Node identifier from which tree traversal will start. If None tree root will be used
- **filter_** – filter function performed on nodes. Nodes excluded from filter function nor their children won't be displayed
- **reverse** – the `reverse` param for sorting `Node` objects in the same level
- **key** – key used to order nodes of same parent
- **reverse** – reverse parameter applied at sorting
- **line_type** – display type choice
- **limit** – int, truncate tree display to this number of lines
- **kwargs** – kwargs params passed to node `line_repr` method

Return type unicode in python2, str in python3

to_dict(*from_=None*, *depth=None*, *with_name=True*)

class pandagg.aggs.**Terms**(**args*, ***kwargs*)
Bases: *pandagg.tree.aggs.aggs.AbstractParentAgg*

KEY = 'serial_diff'

5.2.2 pandagg.connections module

class pandagg.connections.**Connections**
Bases: object

Class responsible for holding connections to different clusters. Used as a singleton in this module.

add_connection(*alias*, *conn*)
Add a connection object, it will be passed through as-is.

configure(***kwargs*)
Configure multiple connections at once, useful for passing in config dictionaries obtained from other sources, like Django's settings or a configuration management tool.

Example:

```
connections.configure(
    default={'hosts': 'localhost'},
    dev={'hosts': ['esdev1.example.com:9200'], 'sniff_on_start': True},
)
```

Connections will only be constructed lazily when requested through `get_connection`.

create_connection(*alias='default'*, ***kwargs*)
Construct an instance of `elasticsearch.Elasticsearch` and register it under given alias.

get_connection(*alias='default'*)
Retrieve a connection, construct it if necessary (only configuration was passed to us). If a non-string alias has been passed through we assume it's already a client instance and will just return it as-is.

Raises `KeyError` if no client (or its definition) is registered under the alias.

remove_connection(*alias*)
Remove connection from the registry. Raises `KeyError` if connection wasn't found.

5.2.3 pandagg.discovery module

class pandagg.discovery.**Index**(*name*, *settings*, *mapping*, *aliases*, *client=None*)
Bases: `object`

search(*nested_autocorrect=True*)

class pandagg.discovery.**Indices**(***kwargs*)
Bases: `lighttree.interactive.Obj`

pandagg.discovery.**discover**(*using*, *index='*'*)

Parameters

- **using** – Elasticsearch client
- **index** – Comma-separated list or wildcard expression of index names used to limit the request.

5.2.4 pandagg.exceptions module

exception pandagg.exceptions.**AbsentMappingFieldError**
Bases: *pandagg.exceptions.MappingError*

Field is not present in mapping.

exception pandagg.exceptions.**InvalidAggregation**
Bases: `Exception`

Wrong aggregation definition

exception pandagg.exceptions.**InvalidOperationMappingFieldError**
Bases: *pandagg.exceptions.MappingError*

Invalid aggregation type on this mapping field.

exception pandagg.exceptions.**MappingError**
Bases: `Exception`

Basic Mapping Error

exception pandagg.exceptions.**VersionIncompatibilityError**
Bases: `Exception`

Pandagg is not compatible with this ElasticSearch version.

5.2.5 pandagg.mapping module

class pandagg.mapping.**Mapping**(**args*, ***kwargs*)
Bases: `pandagg.tree._tree.Tree`

KEY = None

get(*key*)
Get a node by its id. :param nid: str, identifier of node to fetch :rtype: lighttree.node.Node

list_nesteds_at_field(*field_path*)

mapping_type_of_field(*field_path*)

nested_at_field(*field_path*)

node_class
alias of *pandagg.node.mapping.abstract.Field*

node_path(*nid*)

resolve_path_to_id(*path*)

to_dict(*from_=None*, *depth=None*)

validate_agg_node(*agg_node*, *exc=True*)
Ensure if node has field or path that it exists in mapping, and that required aggregation type if allowed on this kind of field. :param agg_node: AggNode you want to validate on this mapping :param exc: boolean, if set to True raise exception if invalid :rtype: boolean

class pandagg.mapping.**IMapping**(**args*, ***kwargs*)
Bases: lighttree.interactive.TreeBasedObj

Interactive wrapper upon mapping tree, allowing field navigation and quick access to single clause aggregations computation.

class pandagg.mapping.**Text**(***body*)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'text'

class pandagg.mapping.**Keyword**(***body*)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'keyword'

class pandagg.mapping.**Long**(***body*)

class pandagg.mapping.**Float**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'float'

class pandagg.mapping.**FloatRange**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'float_range'

class pandagg.mapping.**LongRange**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'long_range'

class pandagg.mapping.**DoubleRange**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'double_range'

class pandagg.mapping.**DateRange**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

KEY = 'date_range'

class pandagg.mapping.**Object**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedComplexField*

KEY = 'object'

class pandagg.mapping.**Nested**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedComplexField*

KEY = 'nested'

class pandagg.mapping.**GeoPoint**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

For lat/lon points

KEY = 'geo_point'

class pandagg.mapping.**GeoShape**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

For complex shapes like polygons

KEY = 'geo_shape'

class pandagg.mapping.**IP**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

for IPv4 and IPv6 addresses

KEY = 'IP'

class pandagg.mapping.**Completion**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

To provide auto-complete suggestions

KEY = 'completion'

class pandagg.mapping.**TokenCount**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

To count the number of tokens in a string

KEY = 'token_count'

class pandagg.mapping.**MapperMurMur3**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

To compute hashes of values at index-time and store them in the index

KEY = 'murmur3'

class pandagg.mapping.**MapperAnnotatedText**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

To index text containing special markup (typically used for identifying named entities)

KEY = 'annotated-text'

class pandagg.mapping.**Percolator**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Accepts queries from the query-dsl

KEY = 'percolator'

class pandagg.mapping.**Join**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Defines parent/child relation for documents within the same index

KEY = 'join'

class pandagg.mapping.**RankFeature**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Record numeric feature to boost hits at query time.

KEY = 'rank_feature'

class pandagg.mapping.**RankFeatures**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Record numeric features to boost hits at query time.

KEY = 'rank_features'

class pandagg.mapping.**DenseVector**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Record dense vectors of float values.

KEY = 'dense_vector'

class pandagg.mapping.**SparseVector**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Record sparse vectors of float values.

KEY = 'sparse_vector'

class pandagg.mapping.**SearchAsYouType**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

A text-like field optimized for queries to implement as-you-type completion

KEY = 'search_as_you_type'

class pandagg.mapping.**Alias**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Defines an alias to an existing field.

KEY = 'alias'

class pandagg.mapping.**Flattened**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

Allows an entire JSON object to be indexed as a single field.

KEY = 'flattened'

class pandagg.mapping.**Shape**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

For arbitrary cartesian geometries.

KEY = 'shape'

class pandagg.mapping.**Histogram**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedRegularField*

For pre-aggregated numerical values for percentiles aggregations.

KEY = 'histogram'

class pandagg.mapping.**Index**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

The index to which the document belongs.

KEY = '_index'

class pandagg.mapping.**Type**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

The document's mapping type.

KEY = '_type'

class pandagg.mapping.**Id**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

The document's ID.

KEY = '_id'

class pandagg.mapping.**FieldNames**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

All fields in the document which contain non-null values.

KEY = '_field_names'

class pandagg.mapping.**Source**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

The original JSON representing the body of the document.

KEY = '_source'

class pandagg.mapping.**Size**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

The size of the _source field in bytes, provided by the mapper-size plugin.

KEY = '_size'

class pandagg.mapping.**Ignored**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

All fields in the document that have been ignored at index time because of ignore_malformed.

KEY = '_ignored'

class pandagg.mapping.**Routing**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

A custom routing value which routes a document to a particular shard.

KEY = '_routing'

class pandagg.mapping.**Meta**(**body)
Bases: *pandagg.node.mapping.abstract.UnnamedField*

Application specific metadata.

KEY = '_meta'

5.2.6 pandagg.query module

class pandagg.query.**Query**(*args, **kwargs)
Bases: pandagg.tree._tree.Tree

Combination of query clauses.

Mapping declaration is optional, but doing so validates query validity and automatically inserts nested clauses when necessary.

Keyword Arguments

- *mapping* (dict or pandagg.tree.mapping.Mapping) – Mapping of requested indice(s). Providing it will add validation features, and add required nested clauses if missing.
- *nested_autocorrect* (bool) – In case of missing nested clauses in query, if True, automatically add missing nested clauses, else raise error.

- remaining kwargs: Used as body in query clauses.

KEY = None

applied_nested_path_at_node(*nid*)

bool(**args*, ***kwargs*)

boost(**args*, ***kwargs*)

constant_score(**args*, ***kwargs*)

dis_max(**args*, ***kwargs*)

filter(**args*, ***kwargs*)

function_score(**args*, ***kwargs*)

has_child(**args*, ***kwargs*)

has_parent(**args*, ***kwargs*)

must(**args*, ***kwargs*)

must_not(**args*, ***kwargs*)

nested(**args*, ***kwargs*)

node_class
alias of *pandagg.node.query.abstract.QueryClause*

parent_id(**args*, ***kwargs*)

pinned_query(**args*, ***kwargs*)

query(**args*, ***kwargs*)
Insert new clause(s) in current query.

Inserted clause can accepts following syntaxes.

Given an empty query:

```
>>> from pandagg.query import Query
>>> q = Query()
```

flat syntax: clause type, followed by query clause body as keyword arguments:

```
>>> q.query('term', some_field=23)
{'term': {'some_field': 23}}
```

from regular Elasticsearch dict query:

```
>>> q.query({'term': {'some_field': 23}})
{'term': {'some_field': 23}}
```

using pandagg DSL:

```
>>> from pandagg.query import Term
>>> q.query(Term(field=23))
{'term': {'some_field': 23}}
```

Keyword Arguments

- *parent* (`str`) – named query clause under which the inserted clauses should be placed.

- *parent_param* (`str` optional parameter when using *parent* param) – parameter under which inserted clauses will be placed. For instance if *parent* clause is a boolean, can be 'must', 'filter', 'should', 'must_not'.
- *child* (`str`) – named query clause above which the inserted clauses should be placed.
- *child_param* (`str` optional parameter when using *parent* param) – parameter of inserted boolean clause under which child clauses will be placed. For instance if inserted clause is a boolean, can be 'must', 'filter', 'should', 'must_not'.
- *mode* (`str` one of 'add', 'replace', 'replace_all') – merging strategy when inserting clauses on a existing compound clause.
  - 'add' (default) : adds new clauses keeping initial ones
  - 'replace' : for each parameter (for instance in 'bool' case : 'filter', 'must', 'must_not', 'should'), replace existing clauses under this parameter, by new ones only if declared in inserted compound query
  - 'replace_all' : existing compound clause is completely replaced by the new one

script_score(**args*, ***kwargs*)

should(**args*, ***kwargs*)

show(**args*, ***kwargs*)

Return tree structure in hierarchy style.

Parameters

- **nid** – Node identifier from which tree traversal will start. If None tree root will be used
- **filter_** – filter function performed on nodes. Nodes excluded from filter function nor their children won't be displayed
- **reverse** – the `reverse` param for sorting `Node` objects in the same level
- **key** – key used to order nodes of same parent
- **reverse** – reverse parameter applied at sorting
- **line_type** – display type choice
- **limit** – int, truncate tree display to this number of lines
- **kwargs** – kwargs params passed to node `line_repr` method

Return type unicode in python2, str in python3

to_dict(*from_=None*, *with_name=True*)

Serialize query as native dict. :param from_: optional, :param with_name: optional :return:

class pandagg.query.**Exists**(**args*, ***kwargs*)

Bases: *pandagg.tree.query.abstract.Leaf*

KEY = 'exists'

class pandagg.query.**Fuzzy**(**args*, ***kwargs*)

Bases: *pandagg.tree.query.abstract.Leaf*

KEY = 'fuzzy'

class pandagg.query.**Ids**(**args*, ***kwargs*)

Bases: *pandagg.tree.query.abstract.Leaf*

KEY = 'ids'

class pandagg.query.**Prefix**(**args*, ***kwargs*)
Bases: *pandagg.tree.query.abstract.Leaf*

KEY = 'prefix'

class pandagg.query.**ScriptScore**(***kwargs*)
Bases: *pandagg.tree.query.abstract.Compound*

KEY = 'script_score'

class pandagg.query.**PinnedQuery**(***kwargs*)
Bases: *pandagg.tree.query.abstract.Compound*

KEY = 'pinned'

5.2.7 pandagg.response module

class pandagg.response.**Aggregations**(*data*, *aggs*, *query*, *index*, *client*)
Bases: object

get(*key*)

keys()

serialize(*output='tabular'*, ***kwargs*)

Parameters

- **output** – output format, one of "raw", "tree", "interactive_tree", "normalized", "tabular", "dataframe"
- **kwargs** – tabular serialization kwargs

Returns

to_dataframe(*grouped_by=None*, *normalize_children=True*, *with_single_bucket_groups=False*)

to_interactive_tree()

to_normalized()

to_tabular(*index_orient=True*, *grouped_by=None*, *expand_columns=True*, *expand_sep='|'*, *normalize=True*, *with_single_bucket_groups=False*)

Build tabular view of ES response grouping levels (rows) until 'grouped_by' aggregation node included is reached, and using children aggregations of grouping level as values for each of generated groups (columns).

Suppose an aggregation of this shape (A & B bucket aggregations):

```
A──> B──> C1
     ├──> C2
     └──> C3
```

With grouped_by='B', breakdown ElasticSearch response (tree structure), into a tabular structure of this shape:

		C1	C2	C3
A	B			
wood	blue	10	4	0
	red	7	5	2
steel	blue	1	9	0
	red	23	4	2

Parameters

- **index_orient** – if True, level-key samples are returned as tuples, else in a dictionnary
- **grouped_by** – name of the aggregation node used as last grouping level
- **normalize** – if True, normalize columns buckets

Returns index, index_names, values

to_tree()

class pandagg.response.**Hit**(*data*)
Bases: object

class pandagg.response.**Hits**(*hits*)
Bases: object

class pandagg.response.**Response**(*data*, *search*)
Bases: object

success

5.2.8 pandagg.search module

class pandagg.search.**MultiSearch**(***kwargs*)
Bases: *pandagg.search.Request*

Combine multiple `Search` objects into a single request.

add(*search*)
Adds a new `Search` object to the request:

```
ms = MultiSearch(index='my-index')
ms = ms.add(Search(doc_type=Category).filter('term', category='python'))
ms = ms.add(Search(doc_type=Blog))
```

execute()
Execute the multi search request and return a list of search results.

to_dict()

class pandagg.search.**Request**(*using*, *index=None*)
Bases: `object`

index(**index*)
Set the index for the search. If called empty it will remove all information.

Example:

s = Search() s = s.index('twitter-2015.01.01', 'twitter-2015.01.02') s = s.index(['twitter-2015.01.01', 'twitter-2015.01.02'])

params(***kwargs*)
Specify query params to be used when executing the search. All the keyword arguments will override the current values. See https://elasticsearch-py.readthedocs.io/en/master/api.html#elasticsearch.Elasticsearch.search for all available parameters.

Example:

```
s = Search()
s = s.params(routing='user-1', preference='local')
```

using(*client*)
Associate the search request with an elasticsearch client. A fresh copy will be returned with current instance remaining unchanged.

Parameters **client** – an instance of `elasticsearch.Elasticsearch` to use or an alias to look up in `elasticsearch_dsl.connections`

class pandagg.search.**Search**(*using=None*, *index=None*, *mapping=None*, *nested_autocorrect=False*)
Bases: *pandagg.search.Request*

aggs(**args*, ***kwargs*)
Arrange passed aggregations "horizontally".

Given the initial aggregation:

```
A──> B
└──> C
```

If passing multiple aggregations with *insert_below* = 'A':

```
A──> B
└──> C
└──> new1
└──> new2
```

Note: those will be placed under the *insert_below* aggregation clause id if provided, else under the deepest linear bucket aggregation if there is no ambiguity:

OK:

```
A──> B ─> C ─> new
```

KO:

```
A──> B
└──> C
```

args accepts single occurrence or sequence of following formats:

- string (for terms agg concise declaration)
- regular Elasticsearch dict syntax
- AggNode instance (for instance Terms, Filters etc)

Keyword Arguments

- *insert_below* (`string`) – Parent aggregation name under which these aggregations should be placed
- *at_root* (`string`) – Insert aggregations at root of aggregation query
- remaining kwargs: Used as body in aggregation

Return type *pandagg.aggs.Aggs*

bool(**args*, ***kwargs*)

count()
Return the number of hits matching the query and filters. Note that only the actual number is returned.

delete() *executes the query by delegating to delete_by_query()*

exclude(**args*, ***kwargs*)
Must not wrapped in filter context.

execute()
Execute the search and return an instance of `Response` wrapping all the data.

filter(**args*, ***kwargs*)

classmethod from_dict(*d*)
Construct a new *Search* instance from a raw dict containing the search body. Useful when migrating from raw dictionaries.

Example:

```
s = Search.from_dict({
    "query": {
        "bool": {
```

(continues on next page)

(continued from previous page)

```
            "must": [...]
        }
    },
    "aggs": {...}
})
s = s.filter('term', published=True)
```

groupby(**args*, ***kwargs*)

Arrange passed aggregations in vertical/nested manner, above or below another agg clause.

Given the initial aggregation:

```
A──> B
└──> C
```

If *insert_below* = 'A':

```
A──> new──> B
      └──> C
```

If *insert_above* = 'B':

```
A──> new──> B
└──> C
```

by argument accepts single occurrence or sequence of following formats:

- string (for terms agg concise declaration)
- regular Elasticsearch dict syntax
- AggNode instance (for instance Terms, Filters etc)

If *insert_below* nor *insert_above* is provided by will be placed between the the deepest linear bucket aggregation if there is no ambiguity, and its children:

```
A──> B      : OK generates     A──> B -> C -> by

A──> B      : KO, ambiguous, must precise either A, B or C
└──> C
```

Accepted all Aggs.__init__ syntaxes

```
>>> Aggs()\
>>> .groupby('terms', name='per_user_id', field='user_id')
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Passing a dict:

```
>>> Aggs().groupby({"terms_on_my_field":{"terms":{"field":"some_field"}}})
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Using DSL class:

```
>>> from pandagg.aggs import Terms
>>> Aggs().groupby(Terms('terms_on_my_field', field='some_field'))
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Shortcut syntax for terms aggregation: creates a terms aggregation, using field as aggregation name

```
>>> Aggs().groupby('some_field')
{"some_field":{"terms":{"field":"some_field"}}}
```

Using a Aggs object:

```
>>> Aggs().groupby(Aggs('per_user_id', 'terms', field='user_id'))
{"terms_on_my_field":{"terms":{"field":"some_field"}}}
```

Accepted declarations for multiple aggregations:

Keyword Arguments

- *insert_below* (`string`) – Parent aggregation name under which these aggregations should be placed
- *insert_above* (`string`) – Aggregation name above which these aggregations should be placed
- *at_root* (`string`) – Insert aggregations at root of aggregation query
- remaining kwargs: Used as body in aggregation

Return type *pandagg.aggs.Aggs*

highlight (**fields*, ***kwargs*)

Request highlighting of some fields. All keyword arguments passed in will be used as parameters for all the fields in the `fields` parameter. Example:

```
Search().highlight('title', 'body', fragment_size=50)
```

will produce the equivalent of:

```
{
    "highlight": {
        "fields": {
            "body": {"fragment_size": 50},
            "title": {"fragment_size": 50}
        }
    }
}
```

If you want to have different options for different fields you can call `highlight` twice:

```
Search().highlight('title', fragment_size=50).highlight('body', fragment_
↪size=100)
```

which will produce:

```
{
    "highlight": {
        "fields": {
            "body": {"fragment_size": 100},
            "title": {"fragment_size": 50}
        }
    }
}
```

highlight_options (***kwargs*)

Update the global highlighting options used for this request. For example:

```
s = Search()
s = s.highlight_options(order='score')
```

must(**args*, ***kwargs*)

must_not(**args*, ***kwargs*)

post_filter(**args*, ***kwargs*)

query(**args*, ***kwargs*)

Insert new clause(s) in current query.

Inserted clause can accepts following syntaxes.

Given an empty query:

```
>>> from pandagg.query import Query
>>> q = Query()
```

flat syntax: clause type, followed by query clause body as keyword arguments:

```
>>> q.query('term', some_field=23)
{'term': {'some_field': 23}}
```

from regular Elasticsearch dict query:

```
>>> q.query({'term': {'some_field': 23}})
{'term': {'some_field': 23}}
```

using pandagg DSL:

```
>>> from pandagg.query import Term
>>> q.query(Term(field=23))
{'term': {'some_field': 23}}
```

Keyword Arguments

- *parent* (`str`) – named query clause under which the inserted clauses should be placed.
- *parent_param* (`str` optional parameter when using *parent* param) – parameter under which inserted clauses will be placed. For instance if *parent* clause is a boolean, can be 'must', 'filter', 'should', 'must_not'.
- *child* (`str`) – named query clause above which the inserted clauses should be placed.
- *child_param* (`str` optional parameter when using *parent* param) – parameter of inserted boolean clause under which child clauses will be placed. For instance if inserted clause is a boolean, can be 'must', 'filter', 'should', 'must_not'.
- *mode* (`str` one of 'add', 'replace', 'replace_all') – merging strategy when inserting clauses on a existing compound clause.
  - 'add' (default) : adds new clauses keeping initial ones
  - 'replace' : for each parameter (for instance in 'bool' case : 'filter', 'must', 'must_not', 'should'), replace existing clauses under this parameter, by new ones only if declared in inserted compound query
  - 'replace_all' : existing compound clause is completely replaced by the new one

scan()
Turn the search into a scan search and return a generator that will iterate over all the documents matching the query.

Use `params` method to specify any additional arguments you with to pass to the underlying `scan` helper from `elasticsearch-py` - https://elasticsearch-py.readthedocs.io/en/master/helpers.html#elasticsearch.helpers.scan

script_fields(***kwargs*)
Define script fields to be calculated on hits. See https://www.elastic.co/guide/en/elasticsearch/reference/current/search-request-script-fields.html for more details.

Example:

```
s = Search()
s = s.script_fields(times_two="doc['field'].value * 2")
s = s.script_fields(
    times_three={
        'script': {
            'inline': "doc['field'].value * params.n",
            'params': {'n': 3}
        }
    }
)
```

should(**args*, ***kwargs*)

size(*size*)
Equivalent to:

```
s = Search().params(size=size)
```

sort(**keys*)
Add sorting information to the search request. If called without arguments it will remove all sort requirements. Otherwise it will replace them. Acceptable arguments are:

```
'some.field'
'-some.other.field'
{'different.field': {'any': 'dict'}}
```

so for example:

```
s = Search().sort(
    'category',
    '-title',
    {"price" : {"order" : "asc", "mode" : "avg"}}
)
```

will sort by `category`, `title` (in descending order) and `price` in ascending order using the `avg` mode.

The API returns a copy of the Search object and can thus be chained.

source(*fields=None*, ***kwargs*)
Selectively control how the _source field is returned.

Parameters **fields** – wildcard string, array of wildcards, or dictionary of includes and excludes

If `fields` is None, the entire document will be returned for each hit. If fields is a dictionary with keys of 'includes' and/or 'excludes' the fields will be either included or excluded appropriately.

Calling this multiple times with the same named parameter will override the previous values with the new ones.

Example:

```
s = Search()
s = s.source(includes=['obj1.*'], excludes=["*.description"])

s = Search()
s = s.source(includes=['obj1.*']).source(excludes=["*.description"])
```

suggest(*name*, *text*, ***kwargs*)

Add a suggestions request to the search.

Parameters

- **name** – name of the suggestion
- **text** – text to suggest on

All keyword arguments will be added to the suggestions body. For example:

```
s = Search()
s = s.suggest('suggestion-1', 'Elasticsearch', term={'field': 'body'})
```

to_dict(*count=False*, ***kwargs*)

Serialize the search into the dictionary that will be sent over as the request's body.

Parameters **count** – a flag to specify if we are interested in a body for count - no aggregations, no pagination bounds etc.

All additional keyword arguments will be included into the dictionary.

update_from_dict(*d*)

Apply options from a serialized body to the current instance. Modifies the object in-place. Used mostly by `from_dict`.

5.2.9 pandagg.utils module

class pandagg.utils.**DslMeta**(*name*, *bases*, *attrs*)

Bases: `type`

Base Metaclass for DslBase subclasses that builds a registry of all classes for given DslBase subclass (== all the query types for the Query subclass of DslBase).

It then uses the information from that registry (as well as *name* and *deserializer* attributes from the base class) to construct any subclass based on it's name.

classmethod get_dsl_type(*name*)

pandagg.utils.**equal_queries**(*d1*, *d2*)

Compares if two queries are equivalent (do not consider nested list orders).

pandagg.utils.**equal_search**(*s1*, *s2*)

pandagg.utils.**get_dsl_class**(*cls*, *name*)

pandagg.utils.**ordered**(*obj*)

5.3 Module contents

CHAPTER 6

Contributing to Pandagg

We want to make contributing to this project as easy and transparent as possible.

6.1 Our Development Process

We use github to host code, to track issues and feature requests, as well as accept pull requests.

6.2 Pull Requests

We actively welcome your pull requests.

1. Fork the repo and create your branch from `master`.
2. If you've added code that should be tested, add tests.
3. If you've changed APIs, update the documentation.
4. Ensure the test suite passes.
5. Make sure your code lints.

6.3 Any contributions you make will be under the MIT Software License

In short, when you submit code changes, your submissions are understood to be under the same MIT License that covers the project. Feel free to contact the maintainers if that's a concern.

6.4 Issues

We use GitHub issues to track public bugs. Please ensure your description is clear and has sufficient instructions to be able to reproduce the issue.

6.5 Report bugs using Github's issues

We use GitHub issues to track public bugs. Report a bug by opening a new issue; it's that easy!

6.6 Write bug reports with detail, background, and sample code

Great Bug Reports tend to have:

- A quick summary and/or background
- Steps to reproduce
  - Be specific!
  - Give sample code if you can.
- What you expected would happen
- What actually happens
- Notes (possibly including why you think this might be happening, or stuff you tried that didn't work)

6.7 License

By contributing, you agree that your contributions will be licensed under its MIT License.

6.8 References

This document was adapted from the open-source contribution guidelines of briandk's gist

pandagg is a Python package providing a simple interface to manipulate ElasticSearch queries and aggregations. It brings the following features:

- flexible aggregation and search queries declaration
- query validation based on provided mapping
- parsing of aggregation results in handy format: interactive bucket tree, normalized tree or tabular breakdown
- mapping interactive navigation

CHAPTER 7

Installing

pandagg can be installed with pip:

```
$ pip install pandagg
```

Alternatively, you can grab the latest source code from GitHub:

```
$ git clone git://github.com/alkemics/pandagg.git
$ python setup.py install
```

CHAPTER 8

Usage

The *User Guide* is the place to go to learn how to use the library and accomplish common tasks. The more in-depth *Advanced usage* guide is the place to go for deeply nested queries.

An example based on publicly available IMDB data is documented in repository *examples/imdb* directory, with a jupyter notebook to showcase some of *pandagg* functionalities: here it is.

The *pandagg package* documentation provides API-level documentation.

CHAPTER 9

License

pandagg is made available under the MIT License. For more details, see LICENSE.txt.

CHAPTER 10

Contributing

We happily welcome contributions, please see *Contributing to Pandagg* for details.
